

Kafka

Kafka Schema Registry

Kafka Schema Registry

Schema Registry enables message producers to comply to a JSON schema and avoid producers from pushing message that are bad into topics. This saves a lot of headache for down-stream consumer. Schema Registry is a critical component in enforcing data governance in a messaging platform.

Steps to add Kafka Registry locally

Step 0: Run the confluent schema registry server using this [docker-compose.yml](#)

Step 1: Add the avro schema files in the producer and consumer resources

Step 2: Add the avro, confluent schema registry related dependencies into the producer and consumer microservices

Step 3: Build the project with the install lifecycle event to auto build the Avro Java class files.

Step 4: Change the serializer and deserializer to the KafkaAvroSerializer
